Overview

Principle Component Analysis is widely used in data exploration, dimension reduction, data visualization. The aim is to transform original data into uncorrelated linear combinations of the original data while keeping the information contained in the data. High dimensional data tends to show clusters in lower dimensional view.

Clustering Analysis is another form of EDA. Here we are hoping to group data points which are close to each other within the groups and far away between different groups. Clustering using PC's can be effective. Clustering analysis can be very subjective in the way we need to summarize the properties within each group.

Both PCA and Clustering Analysis are so called unsupervised learning. There is no response variables involved in the process.

For supervised learning, we try to find out how does a set of predictors relate to some response variable of the interest. Multiple regression is still by far, one of the most popular methods. We use a linear model as a working model for its simplicity and interpretability. It is important that we use domain knowledge as much as we can to determine the form of the response as well as the function format of the factors on the other hand.

Important Notice: This homework encompasses material from three modules. You will have a period of three weeks to complete it. Please manage your time accordingly.

0.1 Objectives

- PCA
- SVD
- Clustering Analysis
- Linear Regression

0.2 Review materials

- Study Module 2: PCA
- Study Module 3: Clustering Analysis
- Study Module 4: Multiple regression (Including Simple regression as well)

0.3 Data needed

- NLSY79.csv
- brca subtype.csv
- brca_x_patient.csv

1 Case study 1: Self-esteem

Self-esteem generally describes a person's overall sense of self-worthiness and personal value. It can play significant role in one's motivation and success throughout the life. Factors that influence self-esteem can be inner thinking, health condition, age, life experiences etc. We will try to identify possible factors in our data that are related to the level of self-esteem.

In the well-cited National Longitudinal Study of Youth (NLSY79), it follows about 13,000 individuals and numerous individual-year information has been gathered through surveys. The survey data is open to public here. Among many variables we assembled a subset of variables including personal demographic variables in different years, household environment in 79, ASVAB test Scores in 81 and Self-Esteem scores in 81 and 87 respectively.

The data is store in NLSY79.csv.

Here are the description of variables:

Personal Demographic Variables

- Gender: a factor with levels "female" and "male"
- Education 05: years of education completed by 2005
- HeightFeet05, HeightInch05: height measurement. For example, a person of 5'10 will be recorded as HeightFeet05=5, HeightInch05=10.
- Weight05: weight in lbs.
- Income87, Income05: total annual income from wages and salary in 2005.
- Job87 (missing), Job05: job type in 1987 and 2005, including Protective Service Occupations, Food
 Preparation and Serving Related Occupations, Cleaning and Building Service Occupations, Entertainment Attendants and Related Workers, Funeral Related Occupations, Personal Care and Service
 Workers, Sales and Related Workers, Office and Administrative Support Workers, Farming, Fishing
 and Forestry Occupations, Construction Trade and Extraction Workers, Installation, Maintenance
 and Repairs Workers, Production and Operating Workers, Food Preparation Occupations, Setters,
 Operators and Tenders, Transportation and Material Moving Workers

Household Environment

- Imagazine: a variable taking on the value 1 if anyone in the respondent's household regularly read magazines in 1979, otherwise 0
- Inewspaper: a variable taking on the value 1 if anyone in the respondent's household regularly read newspapers in 1979, otherwise 0
- Ilibrary: a variable taking on the value 1 if anyone in the respondent's household had a library card in 1979, otherwise 0
- MotherEd: mother's years of education
- FatherEd: father's years of education
- FamilyIncome78

Variables Related to ASVAB test Scores in 1981

Test	Description
AFQT	percentile score on the AFQT intelligence test in 1981
Coding	score on the Coding Speed test in 1981
Auto	score on the Automotive and Shop test in 1981
Mechanic	score on the Mechanic test in 1981
Elec	score on the Electronics Information test in 1981
Science	score on the General Science test in 1981
Math	score on the Math test in 1981
Arith	score on the Arithmetic Reasoning test in 1981
Word	score on the Word Knowledge Test in 1981
Parag	score on the Paragraph Comprehension test in 1981
Numer	score on the Numerical Operations test in 1981

Self-Esteem test 81 and 87

We have two sets of self-esteem test, one in 1981 and the other in 1987. Each set has same 10 questions. They are labeled as Esteem81 and Esteem87 respectively followed by the question number. For example, Esteem81_1 is Esteem question 1 in 81.

The following 10 questions are answered as 1: strongly agree, 2: agree, 3: disagree, 4: strongly disagree

- Esteem 1: "I am a person of worth"
- Esteem 2: "I have a number of good qualities"
- Esteem 3: "I am inclined to feel like a failure"
- Esteem 4: "I do things as well as others"

- Esteem 5: "I do not have much to be proud of"
- Esteem 6: "I take a positive attitude towards myself and others"
- Esteem 7: "I am satisfied with myself"
- Esteem 8: "I wish I could have more respect for myself"
- Esteem 9: "I feel useless at times"
- Esteem 10: "I think I am no good at all"

1.1 Data preparation

Load the data. Do a quick EDA to get familiar with the data set. Pay attention to the unit of each variable. Are there any missing values?

Answer: There are no missing values as there are no null values.

1.2 Self esteem evaluation

Let concentrate on Esteem scores evaluated in 87.

0. First do a quick summary over all the Esteem variables. Pay attention to missing values, any peculiar numbers etc. How do you fix problems discovered if there is any? Briefly describe what you have done for the data preparation.

Answer: For all of the Esteem variables, the minimum value is 1 and the maximum value is 4, which is as expected. There are no missing values. There is nothing to fix.

## [1] 0
```

1. Please note that higher scores on Esteem questions 1, 2, 4, 6, and 7 indicate higher self-esteem, whereas higher scores on the remaining questions suggest lower self-esteem. To maintain consistency, consider reversing the scores of certain Esteem questions. For example, if the esteem data is stored in data.esteem, you can use the code data.esteem[, c(1, 2, 4, 6, 7)] <- 5 - data.esteem[, c(1, 2, 4, 6, 7)] to invert the scores.

Answer: See .rmd document.

2. Write a brief summary with necessary plots about the 10 esteem measurements.

Answer: After correcting the responses such that higher scores correspond to higher self-esteem, we see that all of the questions have more weight towards the right, meaning that most participants gave responses that indicate higher self-esteem. However, questions 6 through 9 have a mass that is more centered around the middle, indicating that respondents have slightly lower self-esteem for these questions.

3. Do esteem scores all positively correlated? Report the pairwise correlation table and write a brief summary.

Value

Answer: All esteem scores are positively correlated; the minimum value in each row is positive. Questions that are adjacent to each other (e.g., questions 1 and 2 or questions 6 and 7) tend to have stronger correlations than questions that are further away from each other.

- 4. PCA on 10 esteem measurements. (centered but no scaling)
 - a) Report the PC1 and PC2 loadings. Are they unit vectors? Are they orthogonal?

Answer: The PC1 loading is (-0.235, -0.244, 0.279, -0.261, 0.312, -0.313, -0.299, 0.393, 0.398, 0.376). The PC2 loading is (0.374, 0.367, -0.149, 0.321, -0.131, 0.209, 0.163, 0.332, 0.578, 0.260). As shown in the table below, PC1 and PC2 both are unit vectors and are orthogonal to each other.

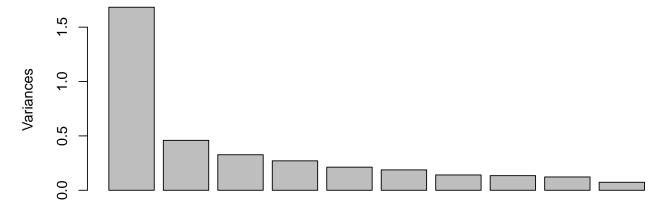

[1] "sdev" "rotation" "center" "scale" "x"

	PC1	PC2
Esteem87_1	0.235	-0.374
${\rm Esteem 87_2}$	0.244	-0.367
$Esteem 87_3$	0.279	-0.149
$Esteem 87_4$	0.261	-0.321
${\rm Esteem 87_5}$	0.312	-0.131
$Esteem 87_6$	0.313	-0.209
$Esteem 87_7$	0.299	-0.163
$Esteem 87_8$	0.393	0.332
${\rm Esteem 87_9}$	0.398	0.578

	PC1	PC2
PC1	1	0
PC2	0	1

pca

b) Are there good interpretations for PC1 and PC2? (If loadings are all negative, take the positive load textcolor{red}{\textbf{Answer:}} We can interpret PC1 as the difference between the total score for Q

c) How is the PC1 score obtained for each subject? Write down the formula.

 $\textcolor{red}{\text{Answer:}} \$PC1 = -0.235 \times (Q1_score) + -0.244 \times (Q2_score) + 0.279 \times (Q1_score) + 0.279 \times (Q1_score) + 0.279 \times (Q1_score) + 0.279 \times (Q1_score) + 0.244 \times (Q1_score) + 0.279 \times (Q1_$

d) Are PC1 scores and PC2 scores in the data uncorrelated?

\textcolor{red}{\textbf{Answer:}} Yes, the PC1 and PC2 scores are uncorrelated. As shown in the table,

e) Plot PVE (Proportion of Variance Explained) and summarize the plot.

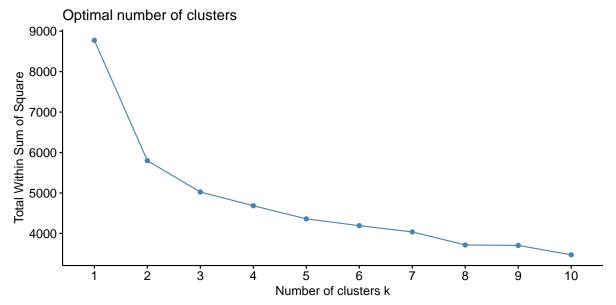

\textcolor{red}{\textbf{Answer:}} The plot shows that PC1 explains almost 50% of the variation and PC2
<!--->

f) Also plot CPVE (Cumulative Proportion of Variance Explained). What proportion of the variance in the \textcolor{red}{\textbf{Answer:}} Approximately 60% of variance in the data is explained by the first 2

<!-- -->

- g) PC's provide us with a low dimensional view of the self-esteem scores. Use a biplot with the first t \textcolor{red}{\textbf{Answer:}} The biplot shows that PC1 roughly corresponds to the difference betwe <!--->
 - 5. Apply k-means to cluster subjects on the original esteem scores
 - a) Find a reasonable number of clusters using within sum of squared with elbow rules.

Answer: Using the elbow method, it appears that 2 is a reasonable number of clusters.

b) Can you summarize common features within each cluster?

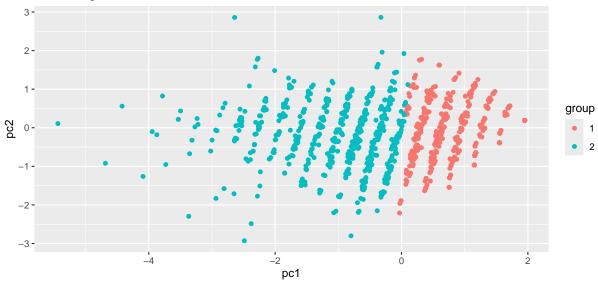

Answer: Cluster 1 is characterized by higher scores for questions 3, 5, 8, 9, and 10. Cluster 2 is characterized by higher scores for questions 1, 2, 4, 6, and 7. This seems to roughly correspond to PC1, which can be interpreted as the approximate difference between the total score for questions 3, 5, 8, 9, and 10 and the total score for questions 1, 2, 4, 6, and 7.

$Group.1 Esteem 87 \underline{E} \underline{\$} teem 87 \underline{E} \underline{\$} $											
1	3.89	3.89	3.90	3.82	3.90	3.78	3.63	3.53	3.49	3.80	1
2	3.37	3.33	3.28	3.20	3.18	3.06	2.96	2.69	2.67	2.96	2

c) Can you visualize the clusters with somewhat clear boundaries? You may try different pairs of variables and different PC pairs of the esteem scores.

Answer: When we cluster by PC1 and PC2, we see a very clear boundary given by PC1. Specifically, group 1 is almost entirely to the left of PC1 = 0, while group 2 is almost entirely to the right of PC2 = 0.

Clustering over PC1 and PC2

- 6. We now try to find out what factors are related to self-esteem? PC1 of all the Esteem scores is a good variable to summarize one's esteem scores. We take PC1 as our response variable.
 - a) Prepare possible factors/variables:
 - EDA the data set first.
 - Personal information: gender, education (05), log(income) in 87, job type in 87. One way to summarize one's weight and height is via Body Mass Index which is defined as the body mass divided by the square of the body height, and is universally expressed in units of kg/m². Note, you need to create BMI first. Then may include it as one possible predictor.
 - Household environment: Imagazine, Inewspaper, Ilibrary, MotherEd, FatherEd, FamilyIncome78. Do set indicators Imagazine, Inewspaper and Ilibrary as factors.
 - You may use PC1 of ASVAB as level of intelligence

\textcolor{red}{\textbf{Answer:}} See .rmd file for code. I created a dataframe that contains all of

- b) Run a few regression models between PC1 of all the esteem scores and suitable variables listed in
 - How did you land this model? Run a model diagnosis to see if the linear model assumptions are reason
 - Write a summary of your findings. In particular, explain what and how the variables in the model af

Answer:

- (i) model4 is my final best model. This model uses PC1 of the esteem scores as the dependent variables and the following as explanatory variables: gender, education level in 2005, log income in 1987, family income in 1978, and PC1 of ASVAB scores. I landed this model by running multiple regression models and looking into the residual and QQ plots. In all the models I ran, the plots provided evidence that the linearity and homoscedasity assumptions are met because the residuals follow a symmetric pattern around h=0 and are evenly distributed within a band. The QQ plot also provided evidence of the normality assumption being met due to the presence of a well fitted straight line. I decided not to use statistical significance as a criterion because the significance did not seem very informative in the model that incorporated all variables, the intercept, IMagazine, and PC1 of the ASVAB scores were statistically significant. Intuitively, whether a family reads a magazine or not should not affect one's self-esteem. Reading a magazine could be correlated to income, and if this is the case, then we would not need to include this redudant variable. Additionally, Ward, Greenhill, & Bakke (2010) show that statistically significant models can actually have very low predictive power; thus, choosing variables based on statistical significance does not seem like a well-informed criterion.
- (ii) When we use model4 as the final best model, we see that gender, education, income, family income, and intelligence all affect one's self-esteem. Specifically, being male and having more education, a higher income in 1987, a higher family income in 1978, and a higher score on the ASVAB as captured by PC1 is associated with having a higher self-esteem, as captured by PC1 of the 1987 esteem scores.

2 Case study 2: Breast cancer sub-type

The Cancer Genome Atlas (TCGA), a landmark cancer genomics program by National Cancer Institute (NCI), molecularly characterized over 20,000 primary cancer and matched normal samples spanning 33 cancer types. The genome data is open to public from the Genomic Data Commons Data Portal (GDC).

In this study, we focus on 4 sub-types of breast cancer (BRCA): basal-like (basal), Luminal A-like (lumA), Luminal B-like (lumB), HER2-enriched. The sub-type is based on PAM50, a clinical-grade luminal-basal classifier. (We had hoped to download the data for control groups for each type of the cancer. But failed to do so. Please let us know if you find the appropriate data.)

- Luminal A cancers are low-grade, tend to grow slowly and have the best prognosis.
- Luminal B cancers generally grow slightly faster than luminal A cancers and their prognosis is slightly
 worse.
- HER2-enriched cancers tend to grow faster than luminal cancers and can have a worse prognosis, but they are often successfully treated with targeted therapies aimed at the HER2 protein.
- Basal-like breast cancers or triple negative breast cancers do not have the three receptors that the other sub-types have so have fewer treatment options.

We will try to use mRNA expression data alone without the labels to classify 4 sub-types. Classification without labels or prediction without outcomes is called unsupervised learning. We will use K-means and spectrum clustering to cluster the mRNA data and see whether the sub-type can be separated through mRNA data.

We first read the data using data.table::fread() which is a faster way to read in big data than read.csv().

- ## brca_subtype
 ## Basal Her2 LumA LumB
 ## 208 91 628 233
 - 1. Summary and transformation
 - a) How many patients are there in each sub-type?

Basal: 208Her2: 91LumA: 628LumB: 233

- b) Randomly pick 5 genes and plot the histogram by each sub-type.
- See plot below
- c) Clean and transform the mRNA sequences by first remove gene with zero count and no variability and then apply logarithmic transform.
- See cleaning procedures below.
- d) Apply PCA to the transformed data. How many PCs should we use and why?
- According to the scree plot, it would be best to use 4 PCs. The plot shows a clear elbow after the 4th PC, and the proportion of variance explained looks significantly lower after the 4th PC.

                         2
                            22 173
```

- 3. Spectrum clustering: to scale or not to scale?
 - a) Apply PCA on the centered and scaled dataset. How many PCs should we use and why? You are encouraged to use irlba::irlba(). In order to do so please review the section about SVD in PCA module.
 - According to the scree plots, it would be best to use 2 PCs.
 - b) Plot PC1 vs PC2 of the centered and scaled data and PC1 vs PC2 of the centered but unscaled data side by side. Should we scale or not scale for clustering process? Why? (Hint: to put plots side by side, use gridExtra::grid.arrange() or ggpubr::ggrrange() or egg::ggrrange() for ggplots; use fig.show="hold" as chunk option for base plots)
 - We should definitely unscale the data. The plot of the centered and scaled data does not show a clear separation between the clusters, while the plot of the centered and unscaled data shows a clear separation between the clusters.

Scree Plot

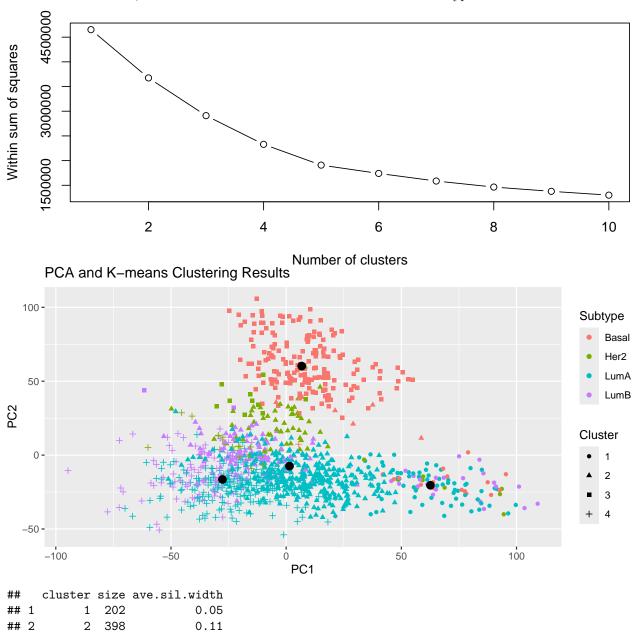

Cumulative Variance Plot

- 4. Spectrum clustering: center but do not scale the data
 - a) Use the first 4 PCs of the centered and unscaled data and apply kmeans. Find a reasonable number of clusters using within sum of squared with the elbow rule.
 - I chose to use 4 clusters because the elbow method suggests that 4 clusters would be appropriate.
 - b) Choose an optimal cluster number and apply kmeans. Compare the real sub-type and the clustering label as follows: Plot scatter plot of PC1 vs PC2. Use point color to indicate the true cancer type and point shape to indicate the clustering label. Plot the kmeans centroids with black dots. Summarize how good is clustering results compared to the real sub-type.
 - According to the plot, the clustering results are respectable (in my limited opinion). I do see some overlap between the clusters, but the true gene types have a lot of overlap which will make it difficult to cluster the data.
 - c) Compare the clustering result from applying kmeans to the original data and the clustering result from applying kmeans to 4 PCs. Does PCA help in kmeans clustering? What might be the reasons

if PCA helps?

- The average silhouette score for the PCA-reduced data is higher than that for the original data, suggesting that PCA does help in kmeans clustering. PCA helps in kmeans clustering because it reduces the dimensionality of the data, which can help to reduce noise and make the clusters more distinct.
- d) Now we have an x patient with breast cancer but with unknown sub-type. We have this patient's mRNA sequencing data. Project this x patient to the space of PC1 and PC2. (Hint: Rmemeber we remove some gene with no counts or no variablity, take log and centered, then find its PC1 to PC4 score) Plot this patient in the plot in b) with a black dot as well. Calculate the Euclidean distance between this patient and each of the centroid of the cluster. (Don't forget the clusters are obtained by using 4 PC's) Can you tell which sub-type this patient might have?
- See below for the graph. I would estimate the sub-type would be LumB, as the patient is closest to cluster 3, which is the cluster that is closest to the LumB sub-type.

3 Case Study: Fuel Efficiency in Automobiles

Linda will refine this case study by the following Monday, Feb 12th)

What determines how fuel efficient a car is? Are Japanese cars more fuel efficient? To answer these questions we will build various linear models using the Auto dataset from the book ISLR. The original dataset contains information for about 400 different cars built in various years. To get the data, first install the package ISLR which has been done in the first R-chunk. The Auto dataset should be loaded automatically. Original data source is here: https://archive.ics.uci.edu/ml/datasets/auto+mpg

Get familiar with this dataset first. Tip: you can use the command <code>?ISLR::Auto</code> to view a description of the dataset. Our response variable will me MPG: miles per gallon.

3.1 EDA

a) Explore the data, list the variables with clear definitions. Set each variable with its appropriate class. For example origin should be set as a factor.

Answer:

Variables and definitions:

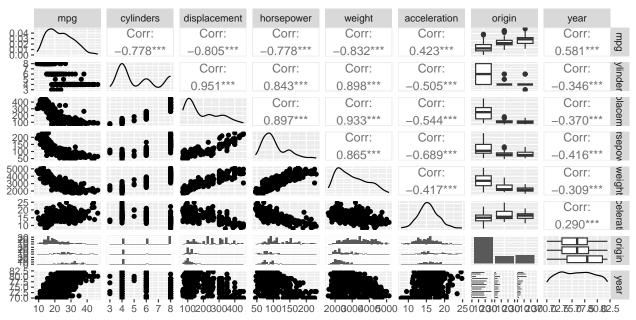

- mpg: miles per gallon
- cylinders: number of cylinders between 4 and 8
- displacement: engine displacement (cubic inches)
- horsepower: engine horsepower
- weight: vehicle weight (lbs)
- acceleration: time to accelerate from 0 to 60 mph (sec)
- year: model year (e.g. 70 for 1970)
- origin: origin of car (1. American, 2. European, 3. Japanese)
- name: vehicle name

Look to .rmd document for the code on EDA and setting variable to appropriate class.

b) How many cars are included in this data set?

Answer: There are 392 cars in the dataset (with 392 unique rows). There are also 301 unique car names in the dataset (that span different model years).

c) EDA, focus on pairwise plots and summary statistics. Briefly summarize your findings and any peculiarities in the data.

Answer:

Summary of variables and findings based on pairwise plots:

- MPG: The distribution of mpg is right-skewed, with a few cars having very high mpg values. MPG is negatively correlated with cylinders, displacement, horsepower, and weight, but positively correlated with acceleration. American cars have the lowest mpg on average, while Japanese cars have the highest mpg on average.
- Cylinders: The distribution of cylinders is right-skewed. cylinders is positively correlated with displacement, horsepower, and weight, but negatively correlated with mpg and acceleration. American cars have the highest average number of cylinders.
- Displacement: The distribution of displacement is right-skewed. displacement is positively correlated with cylinders, horsepower, and weight, but negatively correlated with mpg and acceleration. American cars have the highest average displacement.
- Horsepower: The distribution of horsepower is right-skewed. horsepower is positively correlated with cylinders, displacement, and weight, but negatively correlated with mpg and acceleration. American cars have the highest average horsepower.
- Weight: The distribution of weight is right-skewed. weight is positively correlated with cylinders, displacement, and horsepower, but negatively correlated with mpg and acceleration. American cars have the highest average weight.
- Acceleration: The distribution of acceleration is approximately normal. acceleration is positively correlated with mpg, but negatively correlated with cylinders, displacement, horsepower, and weight.
- Origin: There are more American cars in this dataset. American cars tend to have the highest cylinders, displacement, horsepower, weight, and lowest mpg on average. Japanese cars tend to have the lowest cylinders, displacement, horsepower, weight, and highest mpg on average. European cars tend to have similar characteristics to Japanese cars, but not to American cars.
- Year: The distribution of year is approximately uniform. year is positively correlated with mpg and acceleration, but negatively correlated with cylinders, displacement, horsepower, and weight.

3.2 What effect does time have on MPG?

a) Start with a simple regression of mpg vs. year and report R's summary output. Is year a significant variable at the .05 level? State what effect year has on mpg, if any, according to this model.

```
##
## Call:
## lm(formula = mpg ~ year, data = auto)
##
  Residuals:
##
       Min
                    Median

## F-statistic: 198 on 1 and 390 DF, p-value: <2e-16
```

Answer: Yes, year is a significant variable at the .05 level. The coefficient of year is 1.23, which means that for each additional year, the mpg of a car increases by 1.23 on average. Note that this does not imply a causal link between year and mpg, but an association between the two variables.

b) Add horsepower on top of the variable year to your linear model. Is year still a significant variable at the .05 level? Give a precise interpretation of the year's effect found here.

```
##
## Call:
  lm(formula = mpg ~ year + horsepower, data = auto)

```

Answer: Yes, year is still a significant variable at the .05 level. The coefficient of year is 0.65, which means that for each additional year, the mpg of a car increases by 0.75 on average, holding horsepower constant. This is a smaller effect than the one found in the previous model, which suggests that horsepower is a confounding variable in the relationship between year and mpg, and is correlated with power variables.

c) The two 95% CI's for the coefficient of year differ among (a) and (b). How would you explain the difference to a non-statistician?

Answer: The difference in the 95% CI's for the coefficient of year between the two models is due to the presence of horsepower in the second model. In the first model, there is less precision and more noise in the model since the effect of horsepower isn't taken into account. This results in a wider confidence interval for the coefficient of year in the first model. In the second model, including horsepower in the model makes the model more precise, and so the we can estimate a narrower confidence interval for the coefficient of year is narrower.

d) Create a model with interaction by fitting lm(mpg ~ year * horsepower). Is the interaction effect significant at .05 level? Explain the year effect (if any).

```
##
## Call:
## lm(formula = mpg ~ year * horsepower, data = auto)
##

                 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
## Signif. codes:
##
## Residual standard error: 3.9 on 388 degrees of freedom
## Multiple R-squared: 0.752, Adjusted R-squared: 0.75
## F-statistic: 393 on 3 and 388 DF, p-value: <0.00000000000000000
```

Answer: Yes, the interaction effect is significant at the .05 level. The direct effect (coefficient of year) has now increased to 2.19, and the interaction effect is -0.016. This means that for each additional year, the mpg of a car increases by 2.19 on average, but this effect is reduced by 0.016 for each additional horsepower. This suggests that the effect of year on mpg is moderated by horsepower.

3.3 Categorical predictors

Remember that the same variable can play different roles! Take a quick look at the variable cylinders, and try to use this variable in the following analyses wisely. We all agree that a larger number of cylinders will lower mpg. However, we can interpret cylinders as either a continuous (numeric) variable or a categorical variable.

a) Fit a model that treats cylinders as a continuous/numeric variable. Is cylinders significant at the 0.01 level? What effect does cylinders play in this model?

```
##
## Call:
## lm(formula = mpg ~ cylinders, data = auto)
##
## Residuals:
##
     Min
            1Q
               Median
                        30
                              Max
                      2.549
##
  -14.241
        -3.183
               -0.633
                           17.917
##
## Coefficients:
##
           Estimate Std. Error t value
                                         Pr(>|t|)
## (Intercept)
             42.916
                      0.835
                             -3.558
                      0.146
                            ## cylinders
## ---
## Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 ' ' 1
## Residual standard error: 4.91 on 390 degrees of freedom
## Multiple R-squared: 0.605, Adjusted R-squared: 0.604
```

Answer: Yes, cylinders is significant at the .01 level. The coefficient of cylinders is -3.56, which means that for each additional cylinder, the mpg of a car decreases by 3.56 on average.

However, the interpretation of the model is difficult, because the intercept represents zero cylinders, which is not a meaningful value. Also, cylinders only take on discrete values.

b) Fit a model that treats cylinders as a categorical/factor. Is cylinders significant at the .01 level? What is the effect of cylinders in this model? Describe the cylinders effect over mpg.

```
##
## Call:
## lm(formula = mpg ~ cylinders, data = auto)
##
## Residuals:
##
       Min
                1Q
                    Median
                                 3Q
                                        Max
##
  -11.284
           -2.904
                    -0.963
                              2.344
                                     18.027
##
## Coefficients:
               Estimate Std. Error t value
##
                                                         Pr(>|t|)
## (Intercept)
                 20.550
                              2.349

                                                          0.81071
## cylinders8
                                      -2.33
                                                          0.02015 *
                 -5.587
                              2.395
## Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 ' ' 1
##
```

```
## Residual standard error: 4.7 on 387 degrees of freedom
## Multiple R-squared: 0.641, Adjusted R-squared: 0.638
## F-statistic: 173 on 4 and 387 DF, p-value: <0.0000000000000000</pre>
```

Answer: If cylinders is treated as a categorical variable, the OLS regression will treat each factor as a separate indicator variable. Only cylinders4 is significant at the .01 level. The coefficient of cylinders4 is 8.73, which means that the mpg of a car with 4 cylinders is 8.73 higher on average than a car with 3 cylinders.

It makes sense that only cyliners4 is significant, since the other levels of cylinders have very few observations.

c) What are the fundamental differences between treating cylinders as a continuous and categorical variable in your models?

Answer: The fundamental difference between treating cylinders as a continuous and categorical variable is that the continuous model assumes a linear relationship between cylinders and mpg, while the categorical model assumes that each level of cylinders has a different effect on mpg.

The other main difference is that the continuous model is difficult to interpret, since the intercept represents zero cylinders, which is not a meaningful value. The categorical model is easier to interpret, since each level of cylinders has a separate coefficient.

Personally, we think it is best to use cylinders as a categorical model (where linearity is not assumed), with cylinders4 as the reference level, since it is the most commonly observed level.

d) Can you test the null hypothesis: fit0: mpg is linear in cylinders vs. fit1: mpg relates to cylinders as a categorical variable at .01 level?

```
## Analysis of Variance Table
##
## Model 1: mpg ~ cylinders
## Model 2: mpg ~ cylinders
## Res.Df RSS Df Sum of Sq F Pr(>F)
## 1 390 9416
## 2 387 8544 3 871 13.2 0.000000034 ***
## ---
## Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 ' ' 1
```

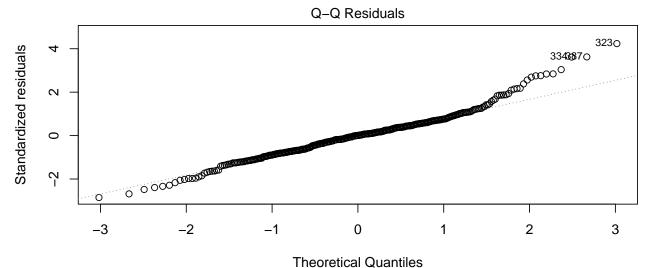

Answer: Yes, we can test the null hypothesis that mpg is linear in cylinders vs. mpg relates to cylinders as a categorical variable at the .01 level using an ANOVA test. The p-value of the test is less than .01 with an F-statistic of 13.2, so we reject the null hypothesis and conclude that the model using cylinders as a categorical variable explains more of the variation and is significantly different from the model modeling cylinders as a linear relationship with mpg.

3.4 Results

Final modeling question: we want to explore the effects of each feature as best as possible. You may explore interactions, feature transformations, higher order terms, or other strategies within reason. The model(s) should be as parsimonious (simple) as possible unless the gain in accuracy is significant from your point of view.

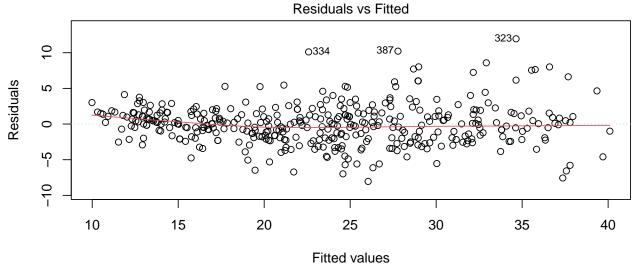

a) Describe the final model. Include diagnostic plots with particular focus on the model residuals and diagnoses.

```

Answer: The final model is a parsimonious linear regression model with mpg as the response variable and log(weight), log(horsepower), years_after_1970, and an interaction term between log(horsepower) and years_after_1970 as the predictor variables. With only three transformed variables and an interaction term, the model has an adjusted R-squared of 0.868 (this is compared to a 0.90 adjusted R-squared in a full model with all variables, log terms, squared terms and two-way interactions).

However, the model's residuals are not normally distributed, as shown by the QQ plot and the Shapiro-Wilk

test. The residuals are also heteroscedastic, as shown by the residual plot and the Breusch-Pagan test. However, even with non-normal residuals and heteroscedasticity, this only causes problems for inference and calculation of standard errors/confidence intervals; OLS is still a unbiased estimator so it is still a valid model for prediction.

b) Summarize the effects found.

Answer:

- log(weight) has a negative effect on mpg, with a coefficient of -17, which means that (roughly) for every 1% increase in weight, mpg decreases by 17
- log(horsepower) has a positive effect on mpg, with a coefficient of 80, which means that for every 1% increase in horsepower, mpg increase by 80. However, one should not interpret this in isolation, because there is an interaction term with year that changes the effect of log(horsepower) on mpg depending on the year of the car.
- years_after_1970 has a positive effect on mpg, with a coefficient of 5.8, which means that for every year increase in the car's model year, mpg increases by 5.8. However, this effect is not constant, as it interacts with log(horsepower).
- The interaction term between years_after_1970 and log(horsepower) has a negative effect on mpg, with a coefficient of -1.1, which means that for every 1% increase in horsepower mpg decreases by 1.1 AND this effect multiplicatively increases for each year after 1970. In essence, the effect of log(horsepower) on mpg is less negative for older cars and more negative for newer cars in the dataset.
- c) Predict the mpg of the following car: A red car built in the US in 1983 that is 180 inches long, has eight cylinders, displaces 350 cu. inches, weighs 4000 pounds, and has a horsepower of 260. Also give a 95% CI for your prediction.

```
## fit lwr upr
## 1 9.65 6.95 12.3
```

Answer: The predicted mpg of the new car is 9.65 with a 95% confidence interval of (6.95, 12.3).

The extremely low predicted mpg is likely due to the fact that the car is high in all of the variables that are negatively associated with mpg (weight, horsepower, displacement and cylinders). However, we should also be extremely careful, the model is extrapolating outside of the range of the data, and should not be trusted. For example, the data has no values for cars with a horsepower over 230 and no values for cars made in 1983, so the model is making predictions based on the assumption that the relationships between the variables are constant outside of the range of the data, which is not a safe assumption.

4 Simple Regression through simulations (Optional)

4.1 Linear model through simulations

This exercise is designed to help you understand the linear model using simulations. In this exercise, we will generate (x_i, y_i) pairs so that all linear model assumptions are met.

Presume that \mathbf{x} and \mathbf{y} are linearly related with a normal error $\boldsymbol{\varepsilon}$, such that $\mathbf{y} = 1 + 1.2\mathbf{x} + \boldsymbol{\varepsilon}$. The standard deviation of the error ε_i is $\sigma = 2$.

We can create a sample input vector (n = 40) for **x** with the following code:

```
# Generates a vector of size 40 with equally spaced values between 0 and 1, inclusive x \leftarrow seq(0, 1, length = 40)
```

4.1.1 Generate data

Create a corresponding output vector for \mathbf{y} according to the equation given above. Use **set.seed(1)**. Then, create a scatterplot with (x_i, y_i) pairs. Base R plotting is acceptable, but if you can, please attempt to use **ggplot2** to create the plot. Make sure to have clear labels and sensible titles on your plots.

4.1.2 Understand the model

- i. Find the LS estimates of β_0 and β_1 , using the lm() function. What are the true values of β_0 and β_1 ? Do the estimates look to be good?
- ii. What is your RSE for this linear model fit? Is it close to $\sigma = 2$?
- iii. What is the 95% confidence interval for β_1 ? Does this confidence interval capture the true β_1 ?
- iv. Overlay the LS estimates and the true lines of the mean function onto a copy of the scatterplot you made above.

4.1.3 diagnoses

- i. Provide residual plot where fitted y-values are on the x-axis and residuals are on the y-axis.
- ii. Provide a normal QQ plot of the residuals.
- iii. Comment on how well the model assumptions are met for the sample you used.

4.2 Understand sampling distribution and confidence intervals

This part aims to help you understand the notion of sampling statistics and confidence intervals. Let's concentrate on estimating the slope only.

Generate 100 samples of size n = 40, and estimate the slope coefficient from each sample. We include some sample code below, which should guide you in setting up the simulation. Note: this code is easier to follow but suboptimal; see the appendix for a more optimal R-like way to run this simulation.

```
y <- 1 + 1.2 * x + rnorm(40, sd = 2)
lse <- lm(y ~ x)
lse_output <- summary(lse)$coefficients
se <- lse_output[2, 2]
b1[i] <- lse_output[2, 1]
upper_ci[i] <- b1[i] + t_star * se
lower_ci[i] <- b1[i] - t_star * se
}
results <- as.data.frame(cbind(se, b1, upper_ci, lower_ci))

# remove unecessary variables from our workspace
rm(se, b1, upper_ci, lower_ci, x, n_sim, b1, t_star, lse, lse_out)</pre>
```

- i. Summarize the LS estimates of β_1 (stored in results\$b1). Does the sampling distribution agree with theory?
- ii. How many of your 95% confidence intervals capture the true β_1 ? Display your confidence intervals graphically.
